 1 /**
   * Main
*/
 2
 3
 4 public class Main {
 6
        public static void main(String[] args) {
 8
             int newScore = Score.calculateScore("Urs", 500);
 9
             System.out.println("New score is " + newScore);
10
             Score.calculateScore(75);
11
             Score.calculateScore();
12
13
14
15
             * Challenge: Calculation of centimeters from feet and inches
16
17
             // Create a method called calcFeetAndInchesToCentimeters
18
            // It needs to have two parameters.
             // feet is the first parameter, inches is the 2nd parameter
19
20
21
22
23
             // You should validate that the first parameter feet is >= 0
            // You should validate that the 2nd parameter inches is >=0 and <=12 // return -1 from the method if either of the above is not true
24
25
            // If the parameters are valid, then calculate how many centimetres
26
                comprise the feet and inches passed to this method and return
27
            // that value.
28
29
            // Create a 2nd method of the same name but with only one parameter
30
            // inches is the parameter
31
32
33
             // validate that its >=0
             // return -1 if it is not true
            // But if its valid, then calculate how many feet are in the inches
// and then here is the tricky part
34
35
             // call the other overloaded method passing the correct feet and inches
36
            // calculated so that it can calculate correctly.
            // hints: Use double for your number datatypes is probably a good idea
            // 1 inch = 2.54cm and one foot = 12 inches
39
             // use the link I give you to confirm your code is calculating correctly.
40
             // Calling another overloaded method just requires you to use the
             // right number of parameters.
41
42
43
